Introduction

This paper focuses on how MATLAB software can be used in signals and systems. There are several MATLAB commands that helps users in understanding the behaviour of certain signals. The design of this project was divided into two different parts. The first task contains seven questions about the continuous time signals and discrete time signals as mathematical expressions which were one of the learning outcomes of our signals and systems in our electrical engineering course. The first task was about the conversion of an analogue audio signal that consists of musical notes into a digital representation by using certain frequencies and expressions. By understanding the instructions given to us we knew every musical note produces a sinusoidal wave, then by the code we created we had to make certain modifications in order to satisfy the given task. One of them was the need of adding an exponential part to the code to make the sound be more sensible and realistic. In the second task, each section was independent of the other, were we had to create certain functions, modify them and plot them. For the second task, each section is independent from one another. Which requires us to use certain functions to plot and test certain applications.

Literature review:

In order to understand how the musical notes, work and how musicians can read them, we watched a video that includes a brief explanation about each note and the location of it. Also, we learned what each symbol means and how can we label each line. By learning this we were able to understand the procedure and hence writing the mathematical expression for each note. The following table shows the given frequencies that we were required to use in order to create our musical piece (Table1).

Note	Frequency(Hz)
A	220
$A^{\#}, B^{b}$	$220*2^{1/12}$
B	$220*2^{2/12}$
C	$220*2^{3/12}$
$C^{\#}, D^{b}$	$220*2^{4/12}$
D	$220*2^{5/12}$
$D^{\#}, E^{b}$	$220*2^{6/12}$
E	$220*2^{7/12}$
F	$220*2^{8/12}$
$F^{\#}, G^{b}$	$220*2^{9/12}$
G	$220*2^{10/12}$
$G^{\#}, A^{b}$	$220*2^{11/12}$

Table 1: Notes in the 220-440 Hz octave.

Task 1

Question 1

Each musical note was presented as a mathematical expression with respect to time. Earlier we identified that the musical notes are sinusoidal waves so the expression is defined to be a sine function multiplied by heaviside function (unit step), and the resultant output should be a rectangular function which makes the splitting of notes easier and smoother. We decided to divide the full note into halves where the beat takes 0.25 seconds and the pause between each note is identified as the given instructions to be 0.25 seconds. In total the musical piece given to us contains 12 notes and 21 pauses in total.

Question 2

For this task, we were required to convert the continuous time signal to discrete time signal by sampling the continuous time signal at a frequency of 8KHz. The discrete time signal is defined as x[N]= x[N*T] where T is the fundamental time period which is equal to the inverse of the 8KHz frequency (1/8000 seconds).

Question 3

For this part, a row vector was constructed which represents the discrete time of the notes. First, we created an empty array or vector and named it y. Then, for loop was created to convert the notes into row vector form. The audiowrite and the audioread commands were used in this task. The empty array is then converted and saved as an audio file using the audiowrite command. However, the audioread command is used to read the selected range of audio samples in the file where the samples are in the form of vector. Finally, the sound command was used to play the musical notes.

Question 4

In this task, an exponential decay function was created to make the volume of the notes decay over time for more realistic output. The exponential decay function was multiplied with the discrete time signal. The exponential decay was represented as exp(-T.*N) with a time period of 1/8000 seconds.

Question 5

In this part, a vector was generated which includes the original signal with the addition of an echo. This echo should occur at T seconds after the original signal starts and must have an amplitude as large the original signal at times. The function that is used to generate the vector was the echogenerator with an amplitude of A and a time delay of Td. The formula used in this part was $s_e = \alpha(t-T)s(t-T)$ which is provided in the project manual. $\alpha(t-T)$ is the attenuation function while $s(t-T)$ is the original signal shifted T units.

Question 6

In this task, an echo was generated to create a reverb effect. The code from question 5 was saved as a function file called echogenerator and used in this task. The attenuation factor and the time delay were given as 0.65 and 0.5 seconds respectively. The sound command was used to display the sound of the music with the effect of reverb.

Question 7

In this task, we were required to compute the time-frequency representation of the continuous time signal from Question 1. This was performed using the spectrogram MATLAB function. The spectrogram produces the musical notes in the frequency domain. The plot identifies the accuracy of the frequency values. The plot shows the relation between the normalized frequency and samples. The x-axis represents the samples while the y-axis represents the normalized frequency in radians per sample. The normalized equation is given as$Frequency\ (Hz) = \frac{1}{2} \times Normalized\ frequency \times sampling\ frequency$which is used to find out the frequency of different colors. The following table shows the frequencies of different colors compared with the musical notes. (Table 2)

Note	**Normalized Frequency**	**Measured Frequency (Hz)**	**Theoretical Frequency (Hz)**
C	0.0625	250	261.6
G	0.09375	375	391.9

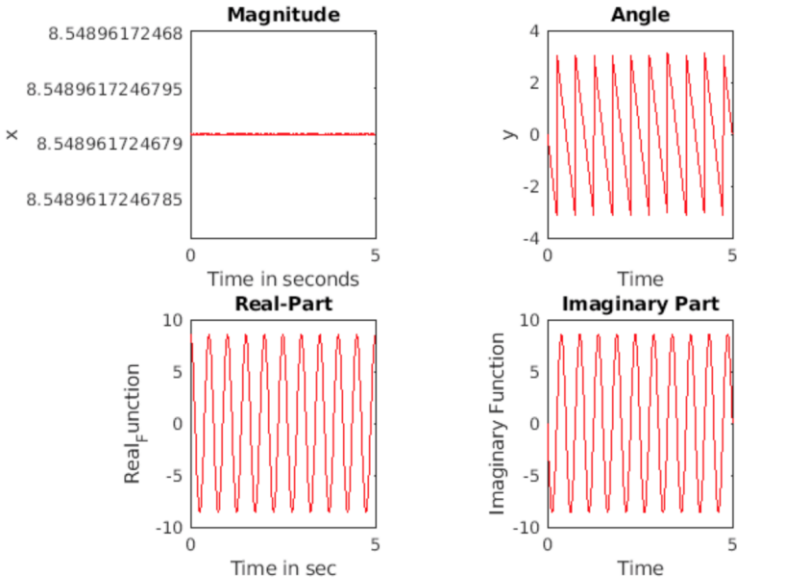
Task 2

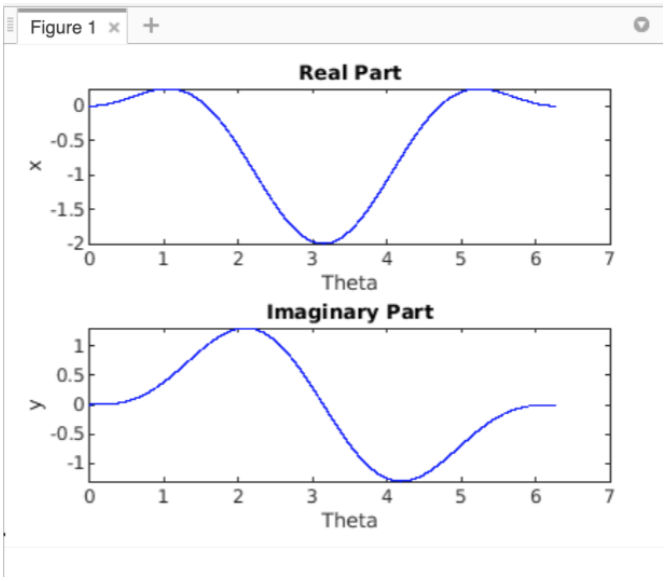
Section 1

In this question, we were required to plot the real and imaginary parts of a complex function, and be familiar with the complex numbers magnitude, real and imaginary parts and the phase angle. In order to compute them we used Angle(ft) to find the phase angle of the given expression. In order to get the magnitude abs was used to get the absolute value. However, in order to distinguish between the real and imaginary parts imag and real were used.



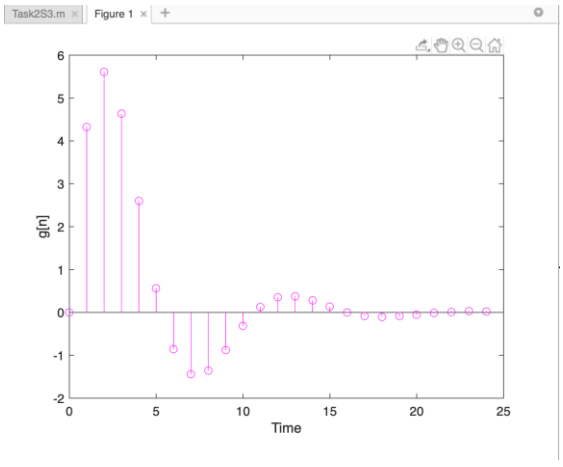
Section 2

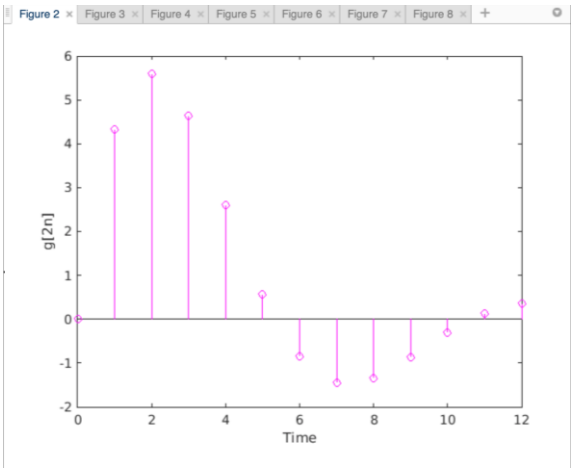
In this question, method used in question 1 was used again to get the imaginary and real parts. In addition to that by using plot and subplots commands in MATLAB. The graphs were plotted.

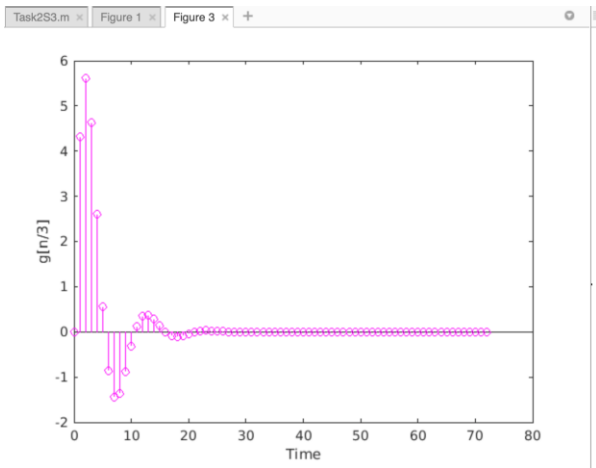


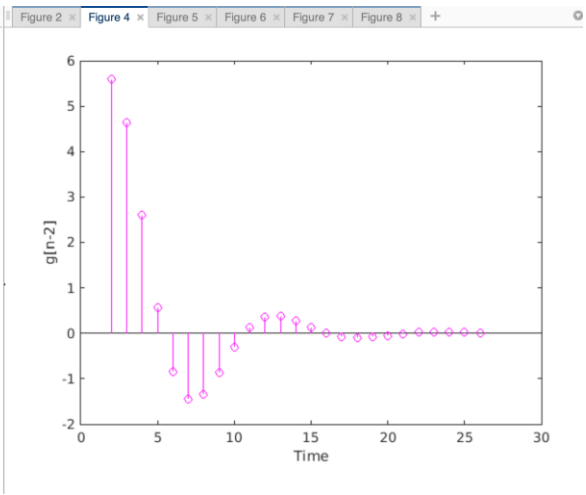
Section 3

In this section, stem function was used, the purpose of this function is used to display data as line starting from the x-axis. A circle by default is inserted in order to represent the value that terminates at each ends of stem. A function was written in MATLAB using the regular script. Then multiple graphs were plotted using stem function to plot discrete time graphs.









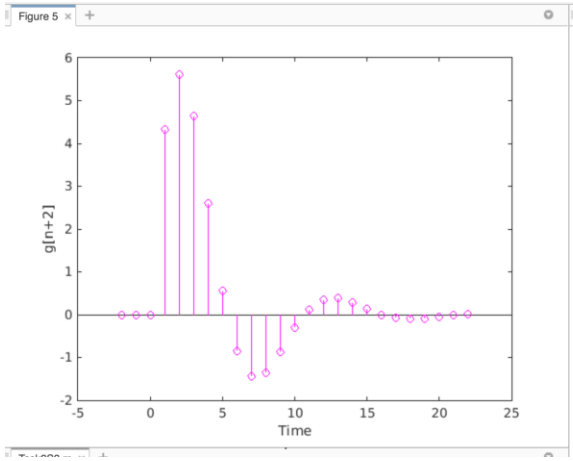


Figure 5
g[n+2]
Time

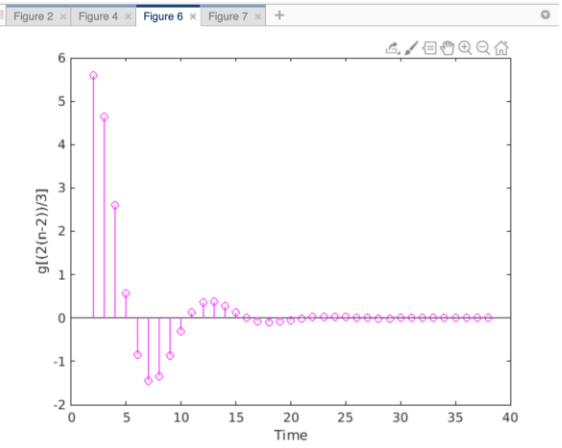

Figure 2
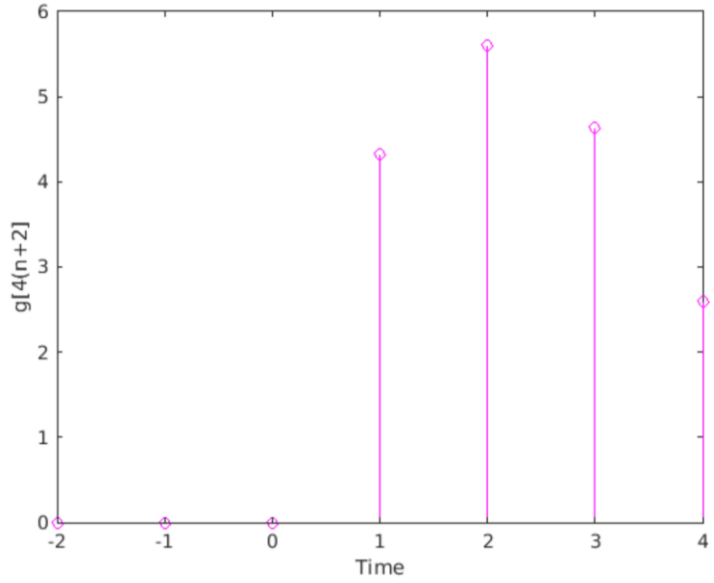
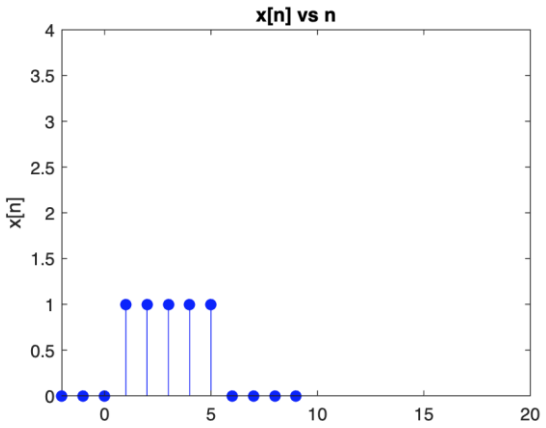
Figure 4
Figure 6
Figure 7
g[(2(n-2))/3]
Time

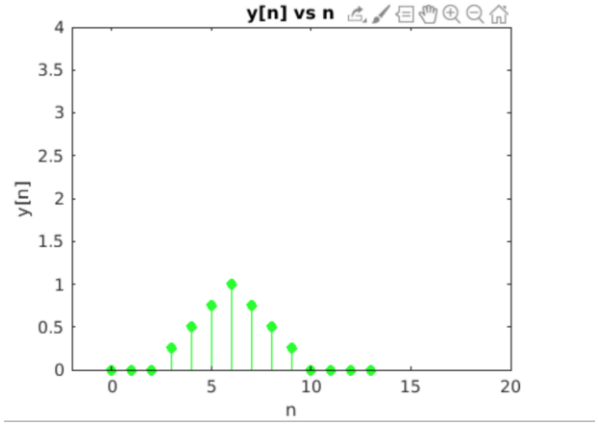


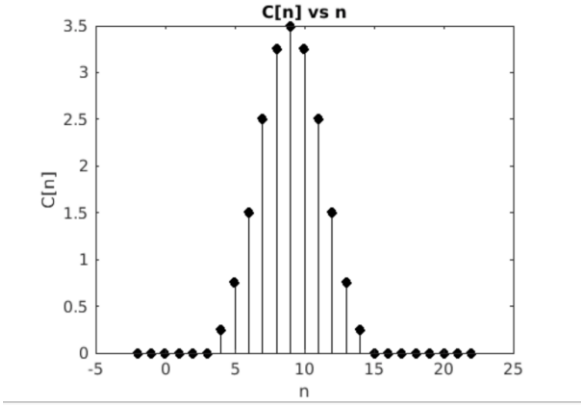
g[4(n+2]
Time

Section 4

The last part of this task is to compute the convolution sum using rectangular pulse and triangular pulse. Using MATLAB functions, triangular pulse was generated by using trangularPulse function. And the rectangular pulse was generated by using rectangularPulse. Finally, the convolution between the rectangular and triangular pulses was generated by using the conv(x,y) function, then the results were plotted using Stem to generate a discrete time vertical lines graphs.







Discussion and Conclusion

This task familiarized us with MATLAB commands that turns out to be useful when solving certain questions in signals and systems, we observed the behavior of signals in each section. The first two sections were dealing with complex numbers.

Finally, this project covered different aspects that we learned in our signals and systems course, we learned theoretically about signals and how they behave. But with this project it gave us an insight about how signals can actually be represented as sine or cosine functions and how the duration of each signal can be controlled using the unit step function. By using the knowledge, we learned from ECEN 314, we were able to express a musical note into a mathematical expression. This mathematical expression was turned into a code in MATLAB to generate an audio, and then implementing certain modifications to make it sound smoother and interesting. Also, the second task we learned how to plot functions and used conv, stem commands. By using these commands, we were able to plot functions in discrete time domain.
